ClipSync AI

A clipboard that does its thinking on your machine.
What it does, how it keeps your data on your device, and how to build and check it yourself.

1 Why this exists

Clipboard tools have a bad habit: they take the most sensitive text on your device, the passwords, one-time codes and half-written messages you copy all day, and send it to a server so the “smart” parts can work. I wanted the opposite. ClipSync AI does its thinking on your own hardware.

No account, no server, no telemetry. Just an app that works with the Wi-Fi off.

At a glance

	What you get	Needs
	Full app: clips, chat, notes, OCR, voice, share sheet, quick tile	4 GB RAM, 1–5 GB for models

2 One app, on your phone

ClipSync AI is an Android app that loads a GGUF model straight into llama.cpp inside its own process. Your phone becomes the AI server: Qwen 0.5B up to Llama 7B, depending on RAM.

- No account, no server, no telemetry — it works with the Wi-Fi off.
- With no model at all, a built-in engine still cleans, classifies and tags every clip, and the app is honest about which buttons need a model and hides the ones that don't.
- Nothing leaves the phone unless you configure a cloud provider yourself. That path is off by default, and the app confirms before sending.

3 What it does, in plain words

Clips

- Automatic capture — everything you copy is kept by a quiet background service.

- Search that understands — keyword search always works, ranked by relevance (titles beat tags, tags beat bodies, rare words beat common ones). Load the small indexing model and the feed ranks by meaning: “that AWS key from last week” finds the key.
- Titles and tags at capture — written by the model when one is loaded, by keywords otherwise.
- Join clips — pick two or more and merge them into one, oldest first, with a divider between parts.
- Redact secrets — one tap masks API keys, tokens, passwords, JWTs and card numbers; auto-redact masks them before a clip is ever saved.
- Duplicate sense — saving something twice asks: keep both, merge into the earlier clip, or discard.
- Clean up, summarise, retitle, pin, copy — with undo where it counts.

Chat, Notes, Capture

- Chat — a real streamed conversation with the on-device model. Attach documents, OCR-read photos, or transcribed voice notes. Cloud providers (OpenAI, Anthropic, Gemini and others) are available only through an explicit, twice-confirmed opt-in.
- Notes — a markdown editor with tags, search, and an AI bar (summarise, expand, fix grammar, action items), every action undoable.
- Capture — camera OCR, dictation, and results you can edit before saving. Share text into Clips from any app’s share sheet, or file the clipboard from a Quick Settings tile without opening the app.

Privacy controls

- App lock — a PIN over the whole app, asked on launch and on every return from the background. Fingerprint or face unlocks it where the hardware exists.
- Clip lifetime — keep clips forever, a day, a week, or a month. Expired, unpinned clips burn on launch. Pinned clips are never dropped.
- Export or wipe — everything out as markdown or JSON, or gone with confirmation.

4 How your stuff stays yours

- On-device inference. The model file lives in your app folder. Words go in, answers come out, nothing in between touches a network.
- Encrypted storage. AES-256 throughout — clips, notes, chats, settings, each with its own key, and the keys live in the system keystore.
- Secrets never land. Auto-redact, per-clip redaction, and lifetimes compose into real defence in depth.

- The ten-second audit. Turn on airplane mode. Everything keeps working except model downloads.

Honest limits

- Models are hungry: small ones want 4 GB of RAM, bigger ones 6–8 GB+, plus room for the weight files.
- The background service shows a quiet notification — Android's rule for anything that keeps working while the app is closed.

5 Build it yourself

Android

```
flutter pub get
flutter build apk --release   # → build/app/outputs/flutter-apk/
```

Check the work

```
flutter analyze && flutter test   # 249 Flutter tests
```

6 Project map

Path	What lives there
lib/main.dart	The app: clips feed, chat, notes, capture, settings, lock screen
lib/services/	On-device LLM, embeddings, biometrics, storage, catalogues
lib/features/ + lib/ui/	History, sheets, and the Liquid Glass design system
android/	Native shell: service, share sheet, quick tile
test/	The test suite
